**Theory and Clinical Application of Continuous Fiberoptic Central Venous Oximetry (ScvO2) Monitoring**

**Physiology and Venous Oximetry**
Maintaining the balance between oxygen delivery (DO2) and consumption (VO2) to the tissues is essential for cellular homeostasis and preventing tissue hypoxia and subsequent organ failure. Traditional monitoring parameters (HR, blood pressure, CVP, and SpO2) have been proven to be poor indicators of oxygen delivery secondary to compensatory mechanisms (Figure 1).1 Moreover, patients have demonstrated continued signs of tissue hypoxia (increased lactate, low ScvO2) even after they have been resuscitated to normalized vital signs.²

![ScvO2 = Early Warning and Prevention](image)

Figure 1. Traditional monitoring parameters failed to alert clinicians to cardiac tamponade in this case.¹

Continuous fiberoptic venous oximetry is a valuable tool for monitoring the balance between oxygen delivery and consumption at the bedside.³ Continuous venous oximetry is a sensitive real-time indicator of this balance, which can be applied as a global or regional indicator – with mixed venous oxygen saturation (SvO2) and central venous oxygen saturation (ScvO2) being the most commonly monitored. SvO2 is a true reflection of the global balance between oxygen delivery and consumption since it is measured in the pulmonary artery, where venous blood returning to the right heart from the superior vena cava (SVC), inferior vena cava (IVC) and the coronary sinus (CS) have mixed. SvO2 has been extensively studied and used clinically to monitor the global balance between DO2 and VO2.²,³,⁴ SvO2 monitoring has been available through either co-oximetry laboratory analysis or through continuous fiberoptic monitoring with advanced technology pulmonary artery catheters since the 1970s and mid-1980s, respectively.
Continuous fiberoptic ScvO₂ monitoring became available in 2003 on an 8.5F central venous catheter platform (PreSep catheter). With the tip of the PreSep central venous catheter placed in the SVC, ScvO₂ can be measured and displayed on either a Vigileo or Vigilance monitor. This capability is also available via 4.5F and 5.5F central venous oximetry catheters (PediaSat catheter) for pediatric use (Figure 2b).

**Difference Between SvO₂ and ScvO₂**
Since SvO₂ and ScvO₂ are affected by the same four factors (cardiac output, hemoglobin, oxygenation, and oxygen consumption), and trend together clinically, they are considered nearly interchangeable.³,⁵ The exception is when calculating global physiologic profiles that use SvO₂, such as VO₂.⁴

SvO₂ is a global indicator of the balance between DO₂ and VO₂ as it is a reflection of all venous blood; IVS, SVC, and CS. ScvO₂ is a regional reflection (head and upper body) of that balance. Under normal conditions ScvO₂ is slightly lower than SvO₂ due in part to the mixing and amount of venous blood retuning. In hemodynamically unstable patients, this relationship changes with ScvO₂ being higher than SvO₂ by approximately 7%.

This difference can widen in shock states, up to 18%, but the values trend together more than 90% of the time.⁵,⁶

**Global Venous Oximetry**  
SvO₂ – mixed venous oximetry  

**Regional Venous Oximetry**  
ScvO₂ – head and upper extremities⁷  
SpvO₂ – peripheral venous oximetry

**Organ Specific Venous Oximetry**  
SjvO₂ – cranial jugular bulb oximetry⁸  
ShvO₂ – hepatic venous oximetry⁹  
ScsO₂ – coronary sinus oximetry¹⁰

**Continuous ScvO₂ Monitoring Technology**
All venous oximetry is measured through reflection spectrophotometry. Light is emitted from an LED through one of the two fiberoptic channels into the venous blood; some of this light is reflected back and received by another fiberoptic channel, which is read by a photodetector. The amount of light that is absorbed by the venous blood (or reflected back) is determined by the amount of oxygen that is saturated or bound to hemoglobin. This information is processed by the oximetry monitor, and updated and displayed every two seconds as a percent value on the monitor (Figure 3).³
**Accuracy of Edwards Fiberoptic Continuous ScvO2 Compared to Co-oximetry**

In a laboratory bench environment continuous fiberoptic venous oximetry monitoring accuracy is approximately ± 2% at oximetry range of 30-99% as compared to a co-oximeter. With oxygen saturations from 9% to 100%, the results of the fiberoptic oximetry systems correlated significantly \( (P < 0.0001) \) with the standard blood gas co-oximetry system \( (r = 0.99) \). In an animal model, fiberoptic ScvO2 technology correlated significantly \( (P = 0.96, P < 0.001) \) and had a close linear relationship as determined by regression analysis \( (r^2 = 0.91, P < 0.001) \). Bland-Altman analysis revealed a + 0.03% difference of means (bias) with ± 4.11% precision. Clinical comparison measurements also showed a significant correlation \( (P = 0.94, P < 0.001) \) and close linear relationship as determined by regression analysis \( (r^2 = 0.88, P < 0.001) \). Difference of means (bias) was - 0.03% with a + 4.41% precision.

**Interference with ScvO2 Readings**

Technical issues and therapeutic interventions may affect fiberoptics. Both the large distal lumen and the sending/receiving optics reside at the tip of the catheter. Therefore, tip position may influence signal quality (SQI) and readings if the tip is positioned against a vessel wall. Fluids infused through the distal lumen may also influence SQI and readings (e.g., lipids such as TPN or propofol, green or blue dyes, and crystalloid infusions at high flow rates). Catheter kinking may also result in a high SQI.

**Interpreting Venous Oximetry (SvO2 and ScvO2) Values**

Normal range values for SvO2 are 60-80% and 70% for ScvO2. ScvO2 usually runs 7% higher than SvO2 in critically ill patients.

Low oximetry readings usually indicate either low oxygen delivery (DO2) or an increase in consumption (VO2). Significantly elevated levels (>80%) may indicate:
- Inability to use oxygen delivered to the tissues (sepsis)
- Significantly high cardiac output
- Shunting of oxygenated blood past tissue
- Technical errors

**When is Change Significant?**

ScvO2 and SvO2 values are not static and fluctuate approximately ± 5%. These values may show significant changes with activities or interventions such as suctioning; however, the values should recover within seconds. Slow recovery is an ominous sign of the cardiopulmonary system’s struggle to respond to a sudden increase in oxygen demand. When monitoring ScvO2, clinicians should look for changes of ± 5 - 10% that are sustained for more than 3-5 minutes and then investigate each of the four factors that influence ScvO2:
- Cardiac output
- Hemoglobin
- Arterial oxygen saturation (SaO2) and
- Oxygen consumption

The first three (above) are indicators of DO2, while the fourth is an indicator of VO2.

**Clinical Applications of ScvO2**

ScvO2 and SvO2 are affected by the same four factors and trend together more than 90% of the time. Thus most of the research and clinical applications documented for SvO2 should apply to ScvO2. Figure 4 provides examples of clinical situations where ScvO2 monitoring may be helpful in identifying imbalances between DO2 and VO2.

---

**Figure 4. Clinical uses of ScvO2 monitoring.**

- **CARDIAC OUTPUT**
  - Hypovolemia
  - Left Ventricular Failure
  - CHF + Pacing
  - High CO + Early Sepsis
  - Low CO + Late Sepsis

- **HEMOGLOBIN**
  - Bleeding + Internal Bleeding
  - Coagulopathies
  - Transfusion

- **OXYGENATION**
  - Ventilation
  - Oxygenation
  - Failure to Tolerate Extubation

- **O2 CONSUMPTION**
  - Burns + Fever
  - Shivering + Seizures
  - Work of Breathing + Sepsis

---
ScvO2 is best used adjunctively with cardiac output monitoring, allowing the clinician to determine the adequacy of oxygen delivery and to differentiate between issues of oxygen delivery vs. oxygen consumption (Figure 5).

**Figure 5. Minimally invasive algorithm breaking down components of oxygen delivery and consumption followed by sub-components investigating root cause of imbalance.**

**Summary**

Continuous venous oximetry (ScvO2) monitoring is an early, sensitive, and real-time indicator of the balance between DO2 and VO2 that can alert clinicians to an imbalance when traditional vital signs may not. ScvO2 monitoring with the PreSep or PediaSat catheter is a practical tool which is no more invasive than a traditional central venous catheter. Venous oximetry is best used in conjunction with cardiac output monitoring. Moreover, keeping ScvO2 values above 70% has been proven to lead to better patient outcomes.14

† PreSep Oligon oximetry catheters contain an integrated Oligon antimicrobial material. The activity of the antimicrobial material is localized at the catheter surfaces and is not intended for treatment of systemic infections. In vitro testing demonstrated that the Oligon material provided broad-spectrum effectiveness (≥ 3 log reduction from initial concentration within 48 hours) against the organisms tested: Staphylococcus aureus, Staphylococcus epidermidis, Klebsiella pneumoniae, Enterococcus faecalis, Candida albicans, Escherichia coli, Serratia marcescens, Acinetobacter calcoaceticus, Corynebacterium diphtheriae, Enterobacter aerogenes, GMRsa, Pseudomonas aeruginosa, Candida glabrata and VRE (Enterococcus faecium).

* SVV is an indicator of preload responsiveness.
